L6 ANSWER 1 OF 8 BIOTECHDS COPYRIGHT 2004 THOMSON DERWENT/ISI on STN

ACCESSION NUMBER: 2004-11063 BIOTECHDS

TITLE: Transfecting cells, useful for treating e.g. autoimmune disorders, blood disorders, or cardiovascular disorders, comprises administering a nucleic acid to salivary gland, and electroporating the salivary gland using electrodes; involving recombinant vector-mediated gene transfer and expression in host cell for use in gene therapy

AUTHOR: TSENG H; BENNETT M J; ROTHMAN S S

PATENT ASSIGNEE: GENTERIC INC

PATENT INFO: US 2003198625 23 Oct 2003

APPLICATION INFO: US 2002-126315 19 Apr 2002

PRIORITY INFO: US 2002-126315 19 Apr 2002; US 2002-126315 19 Apr 2002

DOCUMENT TYPE: Patent

LANGUAGE: English

OTHER SOURCE: WPI: 2004-141541 [14]

AB DERWENT ABSTRACT:

NOVELTY - Transfecting cells comprising administering a nucleic acid to salivary gland, and electroporating the salivary gland by contacting the salivary gland with an electrode comprising 2 needles and pulsing the salivary gland.

BIOTECHNOLOGY - Preferred Method: The nucleic acid is administered by cannulation or by injection via a salivary gland duct, where the salivary gland is a submandibular salivary gland, a parotid salivary gland, or a sublingual salivary gland. The nucleic acid is operably linked to an expression control sequence, and encodes secreted alkaline phosphatase, luciferase, or a therapeutic protein selected from growth hormone, insulin, clotting factor VIII, clotting factor IX, erythropoietin, calcitonin, alpha-galactosidase, alpha-glucosidase, glucocerebrosidase, or immunoglobulin. The needles are about 1 or 0.5 cm apart. The electrode emits an electric field strength of about 1-1000 V/cm, and a pulse length of about 1-60 ms. Pulsing comprises about 1-30 pulses, or 5-6 pulses. Alternatively, the electrode emits an electric field strength of about 100-200 V/cm, and an electrical pulse length of about 10-20 ms. The electroporating step further comprises repositioning the electrode in a second position, and pulsing the salivary gland. The method may further comprise contacting the salivary gland with a second electrode, and pulsing the salivary gland, where the first electrode is in a first position and the second electrode is in a second position. The contacting steps are sequential or simultaneous. A formulant is administered with the nucleic acid, where the formulant is a divalent **transition metal** compound, a polyanionic compound, or a peptide, preferably a divalent **transition metal** compound selected from zinc halide, zinc oxide, zinc selenide, zinc telluride, zinc sulfate, zinc acetate, and zinc chloride. The polyanionic compound is poly-L-glutamate. The formulant is preferably polyvinyl alcohol.

ACTIVITY - Immunosuppressive; Antiarthritic; Antidiabetic; Antiinflammatory; Dermatological; Antianemic; Hemostatic; Antithyroid; Antilipemic; Antianginal; Antiparkinsonian; Nootropic; Neuroprotective; Anorectic; Endocrine-Gen.; Cytostatic; CNS-Gen.; Respiratory-Gen.;

Antiasthmatic; Antibacterial; Virucide. No clinical details given.

MECHANISM OF ACTION - Gene therapy.

USE - The method is useful for treating or preventing autoimmune disorders (e.g. arthritis, diabetes, systemic lupus erythematosus, or Grave's disease), blood disorders (e.g. anemia, or hemophilia), cardiovascular disorders (e.g. high blood pressure, high cholesterol or angina), central nervous disorders (Parkinson's disease, Alzheimer's disease or multiple sclerosis), gastrointestinal disorders (e.g. esophageal reflux, lactose deficiency or defective vitamin B12 absorption), metabolic disorders (e.g. obesity, Hurler's disease, or dwarfism), neoplastic diseases (e.g. cancers or myeloma), pulmonary disorders (e.g. cystic fibrosis, emphysema or asthma), and bacterial (e.g. diphtheria, meningitis or Lyme disease) and viral diseases (e.g. HIV, hepatitis, or chicken pox).

ADMINISTRATION - Administration can be via gravity or an assisted delivery system, or to a salivary gland through a salivary gland duct for retroductal delivery.

ADVANTAGE - Electroporation enhances DNA uptake into salivary gland cells thus increasing the efficiency of gene transfer. Electroporation-mediated in vivo gene transfer systems have provided a new non-viral tool for gene transfer.

EXAMPLE - Male Sprague-Dawley rats were fasted overnight prior to experiment. After anesthesia, both right and left salivary gland ducts were cannulated with fine polyurethane tubing and cemented in place with small drop of Krazyglue. Atropine was administered subcutaneously, and after 10 minutes, NaCl containing 175 microg of luciferase or secreted alkaline phosphatase (SEAP) encoding plasmid DNA with or without formulants was injected retrogradely into each gland through a syringe pump. After DNA delivery into salivary glands, animals to be treated with electroporation were placed in supine position, and a sterile BTX 2-needle **array electrode** was inserted transcutaneously into the center of each gland to a depth of 2-4 mm. Electric pulses generated by an ECM 830 electroporator were applied to glands through this electrode. After electroporation, animals were monitored under a heat lamp until awakening. Salivary gland tissue and blood samples were collected for assay for transgene expression. Luciferase activity in homogenized salivary gland was determined using the Enhanced Luciferase Assay kit. SEAP activity in homogenized salivary gland tissue or plasma was measured using the SEAP Reporter Gene Assay. Expression of luciferase in the rat submandibular gland was enhanced by electroporation as compared to control. Values obtained were approximately 5-6 times greater than the levels of expression in the control group. Additionally, data demonstrates that electroporation enhances SEAP expression by 50-fold. ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS

AB Co, Ni, Pt and Pd nano-wire arrays with diameter of about 50 nm were fabricated by means of template synthesis. By alternating current (AC) elect rodeposition these metals were filled into channels of anodic aluminum oxide (AAO) film respectively. Nano-**electrode**

arrays having good electric contact with the substrate was also fabricated by employing combined electroless deposition and the AC electrodeposition. Strong surface enhanced Raman scattering (SERS) was observed from both metal nano-wire arrays and nano-electrode **arrays** after partial removal of the AAO film. The SERS intensity of probe molecules adsorbed at the arrays depends critically on the length of the nano-wire explored at the surface. The experimental results agree well with the corresponding theoretic calculations based on electromagnetic enhancement. The lightning rod effect may play an important role for the enhancement of the Ni nanorod under the favorable length. It has been shown that metal nano-wire arrays can be developed to a new generation of substrate exhibiting very high SERS activity, especially for **transition metals**. These well-ordered surface nano-structures can also be served as a proper model for the SERS mechanism study. (C) 2002 Elsevier Science B.V. All rights reserved.

AB A method of electrochem. patterning a surface comprises providing an electrolyte overlying the surface and an array of electrodes adjacent the surface and in contact with the electrolyte, and altering the potential of one or more electrodes of the array so as to deposit or remove or chemical modify a substance on the surface adjacent the electrode. Several such treatments can be performed in sequence, using different electrodes of the array. The method is particularly suitable for stepwise chemical synthesis e.g. of oligonucleotides or other oligomers tethered to the surface. **Electrode arrays** for use in the method are also claimed.

OTHER SOURCE: GRA&I9214

AB An electrochemical sensor for nitrogen was developed based on the kinetics of the reaction of a **transition metal** cation, ruthenium (II) aquopentaammine, with molecular dinitrogen. Prototype PN2 sensors were fabricated which incorporate an array of carbon microdisks as the active electrode surface with the smallest probe diameter equivalent to a 23 gauge hypodermic needle. Sensors were characterized on the basis of their electrochemical responses for a diffusion controlled process, the kinetics of the Ru II-N2 complexation reaction, and their operating performance in measuring PN2. In vitro performance tests under equilibrium conditions demonstrated a linear response over a PN2 range of 1 to 10 atmospheric Iterative PN2 measurements

had a +/-5% reproducibility with equilibrium PN2 of 0.77 or 1 atmospheric Under dynamic conditions of changing PN2, the sensor response indicated that the actual concentration of dissolved N2 equilibrates slowly with changes in N2 pressure in the gas phase above the solution, with washout occurring more slowly than washing. Electroanalytical protocols which were satisfactory for early prototypes based on large glassy carbon electrodes must be modified for use with the microdisk array sensors due to the different mass transport properties of microelectrode arrays. Development of standard protocols and a user interface would enhance the utility of the sensor technology to the hyperbaric medical research community.

TITLE: Electrochemical pretreatment of thin film platinum electrodes

AUTHOR(S): Josowicz, Mira; Janata, Jiri; Levy, Max

CORPORATE SOURCE: Inst. Phys., Univ. Bundeswehr Muenchen, Neubiberg, D-8014, Fed. Rep. Ger.

SOURCE: Journal of the Electrochemical Society (1988), 135(1), 112-115

CODEN: JESOAN; ISSN: 0013-4651

DOCUMENT TYPE: Journal

LANGUAGE: English

AB Thin film noble metal electrodes and **electrode arrays** prepared by a photolithog. process suffer from contamination of the surface by traces of **transition metals** and their oxides which are used as adhesion promoters at the insulating substrates. This contamination is an ongoing process as the **transition metals** migrate continuously along the grain boundaries through the thin (1000-4000 Å) layer of the noble metal. The **transition metal** oxide affects the electrochem. properties of the noble metal surface and also its electron work function. A simple electrochem. pretreatment was developed which removes these contaminants from the surface and anneals the surface in a way that acceptable electrochem. behavior identical with a thick noble metal electrode is obtained. It consists of electrochem. etching of the surface by pulsing it between 0 and +2 V in a solution containing 0.08M EDTA, 5.2% NH4OH, and 2.7×10^{-4} M H2O2 for 5-10 min. It is then followed by cycling of the applied potential between +0.4 and -0.4 V in 1M KNO3 for 10 min. Surfaces prepared by this procedure remain clean for a period of at least 24 h.

AB Pt microdisk electrodes of diameter 10'-70 μ m sealed in glass, lying in
 the same plane with Ag pseudoref. and Pt auxiliary disk electrodes, and
 coated with a few micrometers of ionically conducting polymer film
 (poly(ethylene oxide)-LiO₃SCF₃(16:1) containing electroactive solutes provide
 a convenient exptl. microcell format for solid-state linear sweep and
 cyclic voltammetry of the electroactive solutes. Transport rates of the
 solutes in the polymer depend on composition of the bathing (plasticizing) gas
 around the microcell, the temperature (polymer fluidity), and solute charge,
 size, and phys. diffusion vs. electron self-exchange rates. Investigation
 of such transport phenomena requires theor. anal. of the transport
 geometry of the microcell. The preferred situations for measurement of
 transport rate are (1) polymer films thick in comparison to electrode
 diameter and transport rate, so that semiinfinite transport applies, and (2)
 films thin in the same respects, so that currents are a summation of thin
 layer cell and microcylindrical geometries. Measured diffusion consts.
 are confirmed with data from a 4 electrode interdigitated **array**
electrode experiment

AB DERWENT ABSTRACT:

NOVELTY - A reporter system (I) to detect nucleic acid containing **analyte** (A) in liquid has: (i) capture oligonucleotides (II) immobilized on a solid support and capable of specifically binding (A); (ii) affinity systems comprising an affinity component capable of specifically binding to (A) and/or (II); and (iii) an electrochemical sensor.

DETAILED DESCRIPTION - A reporter system (I) for detecting a nucleic acid containing **analyte** (A) present in a liquid, comprises: (a) capture oligonucleotides (II) (2) immobilized on a solid support (1) and capable of specifically binding (A); (b) affinity systems containing encapsulated electrochemically detectable reporter molecules (III), chosen from: (i) affinity liposomes (IV) containing (III) and comprising a surface-attached affinity component capable of specifically binding to (A) and/or (II) in a condition where (A) and (II) are bound to each other, but not to free (II); (ii) polymeric carrier molecules containing a **covalently** linked affinity component capable of specifically binding to (A) and/or (II) in a condition, where (A) and (II) are bound to each other, but not to free (II), and a **covalently** linked affinity component capable of specifically binding to affinity liposomes, plus affinity liposomes (V) containing encapsulated electrochemically detectable reporter molecules and comprising a surface-attached affinity component capable of specifically binding to the polymeric carrier molecules; (iii) complexes of (IV); and (iv) polymeric carrier molecules containing a **covalently** linked affinity component capable of specifically binding to (A) and/or (II) in a condition, where (A) and (II) are bound to each other, but not to free (II), and a **covalently** linked affinity component capable of specifically binding to affinity liposomes of complexes of affinity liposomes, plus the complexes of (IV); and (c) an electrochemical sensor.

WIDER DISCLOSURE - A kit comprising the reporter system, for detecting nucleic acid containing **analyte** in a liquid sample, is also disclosed.

BIOTECHNOLOGY - Preferred Reporter System: A surface-attached affinity component(s) of (IV) is chosen from single-stranded RNA or DNA, single-stranded RNA or DNA oligonucleotides, preorganized oligonucleotide structures including peptide nucleic acid (PNA) analogs, intercalating agents, intercalating agents conjugated to single-stranded oligonucleotides or nucleic acids, immunoglobulins or its fragments with specificity for double- and/or triple-stranded nucleic acids, and

non-immunoglobulin proteins capable of specifically binding to double-stranded nucleic acids. The surface-attached affinity component(s) is/are an intercalating agent chosen from acridines, actinomycin D, anthracyclines, cyanine dyes, hydroxystilbamidine, imidazoles, indoles, phenanthridines, psoralens or their derivatives. The **covalently** linked affinity component of the polymeric carrier molecules capable of specifically binding to the affinity liposomes is haptens, anti-haptens antibodies, enzyme inhibitors, inhibitor-binding enzymes, biotin, avidin or streptavidin. The surface-attached affinity components of the affinity liposomes are haptens, anti-hapten antibodies, enzyme inhibitors, inhibitor-binding enzymes, biotin, avidin or streptavidin. The complexes of (IV) are formed from affinity liposomes containing two types (type I and type II) of surface-attached affinity components, type I surface-attached affinity components being capable of specifically binding to (A) and/or the capture molecules in a condition, where (A) and capture molecules are bound to each other, but not to free capture molecules, and the type II surface-attached affinity components being capable of mediating the complexation of affinity liposomes by bridging molecules which have two binding sites for type II affinity components. Optionally, the type II surface-attached affinity components are capable of mediating the complexation of affinity liposomes by polymeric carrier molecules with immobilized affinity components providing two binding sites for type II affinity components. The surface-attached type II affinity components capable of mediating the complexation of affinity liposomes by bridging molecules are haptens, enzyme inhibitors or biotin. The bridging molecules are selected from molecules with more than a binding site, preferably from bi- or oligovalent anti-hapten antibodies, their fragments, conjugates, fusion constructs, inhibitor-binding enzymes, conjugates, fusion constructs and avidin and streptavidin. The surface-attached type II affinity components capable of mediating the complexation of (II) by polymeric carrier molecules, and the affinity components immobilized on the polymeric carrier molecules are chosen from haptens, anti-hapten antibodies, enzyme inhibitors, inhibitor-binding enzymes, biotin, avidin and streptavidin. Optionally, the complexes of (IV) are formed from two types of affinity liposomes, type I affinity liposomes containing two surface-attached affinity components capable of specifically binding to (II), and type II affinity liposomes containing two surface-attached affinity components capable of specifically binding to the surface-attached affinity components of type I affinity liposomes. Preferably, the type I affinity liposomes are chosen from single-stranded RNA and DNA, single-stranded RNA and DNA oligonucleotides, preorganized oligonucleotide structures including peptide nucleic acid (PNA) analogs capable of forming specific helical complexes with specific target nucleic acids or their amplicons, and the affinity components of type II affinity liposomes are as type I liposomes capable of forming helical complexes with the oligonucleotides and preorganized oligonucleotide structures of type I affinity liposomes. Complexes of (V) are formed from affinity liposomes containing two types of surface-attached affinity components such as surface-attached type I affinity components, and type II affinity components which are capable of mediating the complexation of affinity liposomes by bridging molecules. Optionally, the complexes of (V) are formed from affinity liposomes containing two types of surface-attached affinity components such as surface-attached type I affinity components, and type II affinity components which are capable of mediating the complexation of affinity liposomes by polymeric carrier molecules.

USE - (I) is useful for detecting a nucleic acid containing (A) in a liquid sample comprising: (a) providing (I) comprising capture oligonucleotides, affinity systems, preferably comprising affinity liposomes (IV) containing detectable reporter molecules (III), and an electrochemical sensor; (b) contacting the sample with immobilized capture oligonucleotides; (c) adding the affinity systems containing electrochemically detectable reporter molecules; (d) removing unbound affinity liposomes; (e) releasing encapsulated (III) from the interior of

affinity liposomes; and (f) measuring the reporter molecules using the electrochemical sensor. Preferably, (III) is released from the interior of the liposome by increasing the ambient temperature or by adding a liposome-lyzing agent. The method further comprises: (a) adding polymeric carrier molecules capable of specifically binding to (A) and/or (II) in conditions where (A) and (II) are bound to each other but not to free (II); and (b) removing unbound polymeric carrier molecules, before adding the affinity systems containing (III), and where the affinity liposomes added are capable of specifically binding to (A)-bound polymeric carrier molecules (claimed).

ADVANTAGE - The detection system eliminates the necessity for optical clarity of the sample solution and other ambient optical density requirements, and the necessity of enzymatic amplification technology. One small affinity liposome provides 10⁵ molecules of redox mediators to allow excellent detectability of a binding event. The signal provided by a single **analyte**-bound affinity liposome can be easily amplified by one to two orders of magnitude if polymeric carrier systems and/or preformed complexes of affinity liposomes are used for detection. There is no need for chemical derivatization of redox mediators using the non-enzymatic liposome-linked interdigital **array electrodes array**. As a result, (I) reduces costs and analysis time without compromising detection sensitivity.

EXAMPLE - Detection of Mycobacterium tuberculosis DNA using oligonucleotide-affinity liposomes was carried out as follows. The single-stranded (ss) oligonucleotides complementary to the 3'-terminus of short fragments from the direct-repeat region of the M. tuberculosis DNA were **covalently** immobilized onto silica beads to serve as capture oligonucleotides. Captured M. tuberculosis DNA was detected with ss oligonucleotide-affinity liposomes containing p-aminophenol. The liposome-attached oligonucleotides were complementary to the 5'-terminus of short fragments from the direct-repeat region of M. tuberculosis DNA. Bound liposomes were lyzed by the addition of detergent and released p-aminophenol (PAP) was quantified by redox recycling using interdigitated array (IDA) electrodes. The assay was performed as a combination of liquid chromatography with electrochemical detection (LCEC). The ss capture oligonucleotide (18-mer) used in the assay was an oligonucleotide complementary to the 3'-terminus of the short fragment from the direct-repeat region of the M. tuberculosis DNA and included at the 3'-terminus, a 2-base thiophosphate thymine-Ts tag for immobilization to tresyl-activated silica beads and a single T-base separating the tag from the sensing oligonucleotide sequence: 3'-tsttcagcagctctgggttttgg-5'. The other assay components were a short fragment (36-mer) from the direct-repeat region of the M. tuberculosis DNA 5'-gtcgtcagaccccaaaaccccgagaggggacggaaac-3' and ss liposome-attached oligonucleotide (18-mer: 3'-ggctctcccctgcctttg-5'-pyridyl disulfide) which was complementary to the 5'-terminus of the short fragment from the direct-repeat region of M. tuberculosis DNA and included at the 5'-terminus a pyridyl disulfide residue for **covalent** coupling to sulfhydryl-derivatized affinity liposomes. The thiophosphate thymine-containing capture oligonucleotides were immobilized onto tresyl-activated silica beads. Sulfhydryl-derivatized affinity liposomes were prepared by an injection method (Biochim.Biophys.Acta 298, 1015, 1973) from a lipid mixture of dimyristoylphosphatidylcholine, cholesterol, dicetylphosphate at a molar ratio of 5:4:1, and phosphatidylethanolamine derivatized with succinimidyl acetylthiopropionate (PE-SATP) at a concentration of 0.5 mol % of total lipid. To prepare liposomes, 2 micromol of stock lipid mixture in chloroform was evaporated under a stream of nitrogen and then placed in a vacuum desiccator overnight. The lipid was resolubilized in 50 microliters of dry isopropanol and injected with a syringe into 1 ml of 10 mM N-(2-OH-ethyl-)piperazine-N'-(2-ethanesulfonic acid) (HEPES), pH 7.4, containing 50 mM aminophenol. Liposomes of uniform size were formed spontaneously by this method. Unencapsulated p-aminophenol was removed by gel filtration, and liposomes were suspended in 0.1 M sodium phosphate,

0.15 M NaCl, pH 7.5, at a concentration of 5 mg/ml and mixed with hydroxylamine hydrochloride. After 2 h at room temperature, the deacetylated liposomes were purified by gel filtration and used immediately for coupling of pyridyl disulfide-derivatized oligonucleotides to the surface-attached sulfhydryl groups. The analytical system was washed and then the valve connecting the hybridization chamber with the flow chamber was closed and the sample containing the short fragment (36-mer) from the direct-repeat region of the M. tuberculosis DNA was applied to the hybridization chamber. After an incubation for 1 h at room temperature, the hybridization chamber was washed again with several volumes of 20 mM sodium phosphate, 0.1 M NaCl, pH 7, captured M. tuberculosis DNA was detected by adding 50 microliters of oligonucleotide-affinity liposomes. After an incubation of 1 h at room temperature, the hybridization chamber was washed with several volumes of 20 mM sodium phosphate, 0.1 M NaCl, pH 7. Finally, the valve connecting the immunoreaction chamber with the flow chamber was opened and bound affinity liposomes were lysed by the addition of 100 microliters of 10 mM sodium phosphate, pH 7, containing 0.01 % Triton X-100. Released p-aminophenol (PAP) was detected by redox recycling. PAP was oxidized to quinoneimine at the anode (+250 mV) yielding an oxidation current. At the cathode (-50 mV) the quinoneimine was reduced to PAP. Using redox cycling for the detection of PAP, the detection limit was in the range of 50 nM corresponding to 2.5 pmol per 50 microliters. Since 10 to the power of 4 - 10 to the power of 5 p-aminophenol molecules are released from a single bound oligonucleotide-affinity liposome, the described assay configuration allowed the detection of low nanogram quantities/ml of the short fragment (36-mer) from the direct-repeat region of the M. tuberculosis DNA. AB Procedures and results are described for multiplexed immunochemical assays using semiconductor microchips. The microchips used here are miniaturized arrays of individually addressable microelectrodes controlled by active CMOS circuitry. Electrode densities exceed 1000 per cm(2). The array chips are coated with a porous reaction layer material to provide a 'biofriendly' milieu overlaying the **electrode array**. Biotin is linked **covalently** to regions within the porous reaction layer proximate to selected microelectrodes. **Covalent** linkage is accomplished using reagents that are generated in situ by the microelectrodes. The **covalent** linkage of biotin within the porous reaction layer allowed traditional streptavidin (SA)-based immunoassay formats to be used on the biochips. Biochips were used to develop multiplexed assay formats for biological entities over a wide size range - from small organic molecules to cells. Sandwich immunoassays were used for larger entities and competitive immunoassays for smaller molecules. Detection of **analytes** was accomplished using fluorophore-tagged antibodies and epifluorescent microscopy. Results from a broad range of **analytes** are presented. .COPYRGHT. 2001 Elsevier

AB CombiMatrix employs CMOS integrated circuitry to produce analog VLSI arrays of individually addressable electrodes. First generation **electrode ArrayChips** provide 1,000 electrodes per square centimeter. The chips are coated with a porous biomatrix that is modified electrochem. to immobilize biotin at selected sites. The **covalent** linkage of biotin to the biomatrix allows traditional streptavidin-based immunoassay formats to be used on the chip. ArrayChips are used to develop multiplexed assay formats for biol. entities over a wide size range; from proteins to cells. Sandwich immunoassays are used for larger entities and competitive immunoassays for smaller mols. Detection of **analytes** is accomplished using fluorophore-tagged antibodies and epifluorescent microscopy. Results from a wide range of **analytes** will be discussed.

AB Chemical and biol. sensors are provided that convert the chemical potential energy of an **analyte** into a proportionate elec. signal through the transducer action of a microfabricated device with an integral electroconductive polymer film. The microsensor devices possess a coplanar arrangement of at least one, and typically three, microfabricated interdigitated microsensor **electrode arrays** each with line and space dimensions that may range from 2-20 μm and is typically 10 μm , a platinized platinum counter electrode of area at least 10 times the area of the interdigitated microsensor **electrode array** and a chloridized silver/silver chloride reference electrode. Chemical and biol. sensors constructed according to the present invention employ a thin elec. conducting polymer film that is specifically attached via **covalent** bond formation to the interdigitated microsensor electrode component of the devices. The elec. conducting polymer film is

formed in three layers, the first layer possesses high elec. conductivity and is

covalently attached to the device surface, the second layer possess an inorg. catalyst and is **covalently** attached to the first, and the third layer possesses an indicator mol. which may be a bioactive mol. such as an enzyme or member of specific binding pair of biol. origin and is itself **covalently** attached to the second layer. Binding of an **analyte** or member of the specific binding pair reagent may result in a change in the elec. impedance (resistance and capacitance or both) of the highly elec. conducting layer. The elec. change in the polymer layers is a sensitive measure of the extent of binding of the binding agent and forms an anal. signal for the binding agent.
